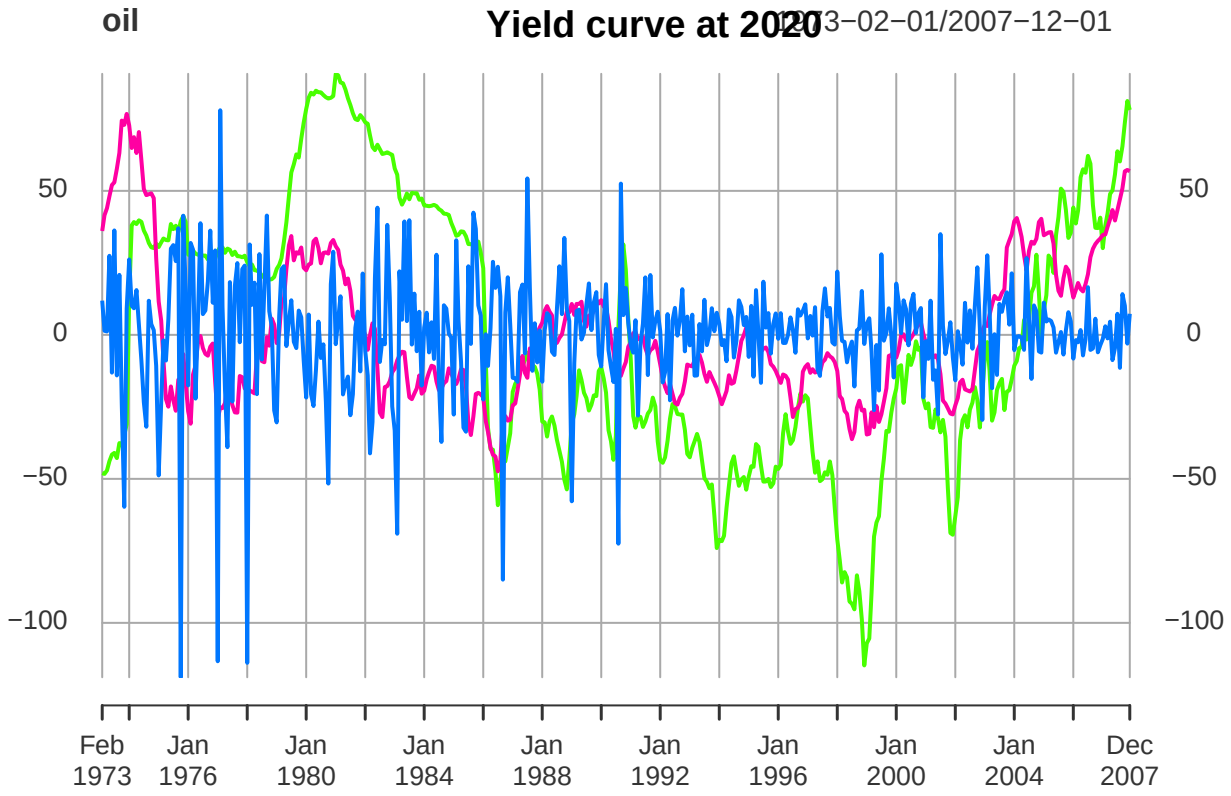
Assignement

Point 1

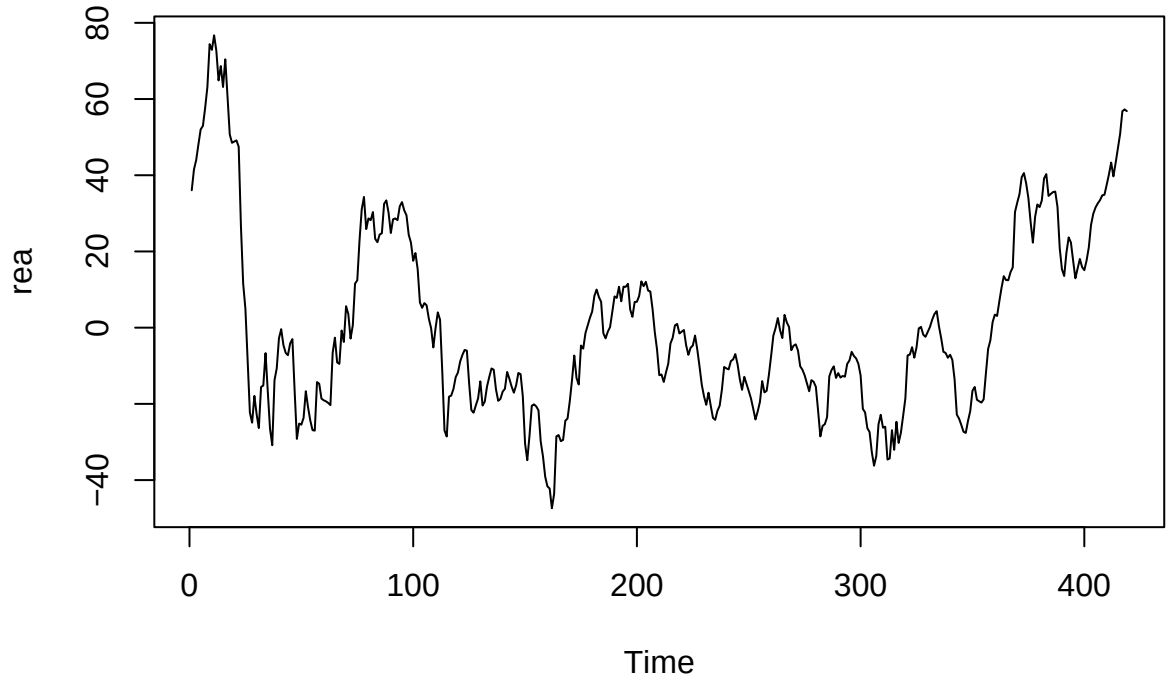
The time series below represents the monthly time series of: 1. % change in global crude oil production 2. the real price of oil 3. the real economy activity From 1973:1 to 2007:12.



As we can see the acf its clear signaling the presence of an autcorrelation process. In order to test if the rea is an $I(1)$, we will use an ADF test with lag =1. We will perform the test specifing four different type of the process: 1. No consant, no trend 2. Constant 3. Constant with trend 4. No costant with trend First, we print the first times series graph. We perform the different type of the test with a maximun lag order of 12:

$$rea_t = \alpha + \sigma_1 reat_(t-1) + ... + \sigma_1 2\delta reat_(t-13)$$

We take the model with constant, otherwise the model will be too restricive, and without time trend, selectin the



one which as lower BIC:

```

As we can see from the table above which report the result of the ADF tests, it is clear that the process is not stationary with a $alpha < 10$, so there are no sufficent empirical evidence to reject the null. Thus the *rea* time series is not a covariance-stationary process with a minium lag of order 1.

Point 2

We take the first difference of the timeseries *rea* and check if it is stationary with an adf test. Before that we print the time series of the first differences, the acf, and the pacf to understat the correct specification for the ADF test.

Lag

The above graphs clearly underline stationarity of the process, indeed the acf for the $lag > 2$ the partial autcorrelation is not statisticaly different from 0. As for the partial autcorrelation that is statistically different only for some lag>10. From the plot of the time series we can see a mean reverting process, and so I will opt for the specifications with constant, becouse it is less restricitve. so the test will have the following specifications:

$$\delta rea_t = \alpha + \sigma_1 \delta reat_(t-1) + ... + \sigma_1 2 \delta reat_(t-13)$$

$$\delta rea_t = \alpha + \beta * t + \sigma_1 \delta reat_(t-1) + ... + \sigma_1 2 \delta reat_(t-13)$$

The test will be performed with all passible four specification, and will be selected the specification with lower adf value.
